

LM8207

LM8207 TFT 18 Gamma Buffer + VCOM Driver + Voltage Reference

Literature Number: SNOSAL5

LM8207

TFT 18 Gamma Buffer + V_{COM} Driver + Voltage Reference

General Description

The LM8207 is a combination of 18-channel gamma buffers, a V_{COM} driver and a temperature compensated internal voltage reference. It is designed for buffering voltage levels and driving high capacitive loads in large TFT panels. The gamma buffers are individually optimized to the input/output requirements of their respective gamma position to cover the whole voltage range from rail to rail. Any desired gamma correction curve can be obtained by combining the gamma buffers with external resistors. The V_{COM} driver has a high output current capability and is stable with large capacitive loads, typical for large panel sizes. This will result in a fast recovery time for large voltage variations at the output. The internal band gap reference can be used to form a highly stable voltage to generate the gamma correction voltages. In combination with the internal amplifier, the reference voltage can be programmed to voltages up to the positive rail. The LM8207 is offered in a 48-pin TSSOP package.

Features

- Gamma buffers 1-2 swing to V_{DD}
- Gamma buffers 17-18 swing to V_{SS}
- Large output current V_{COM} driver ($I_{SC} = 300\text{ mA}$)
- Stable (1%) internal 1.295V reference, to improve picture quality and reduce variations
- 48-pin TSSOP package

Applications

- TFT gamma curve connection and V_{COM} voltage buffering

Absolute Maximum Ratings (Notes 1, 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/ Distributors for availability and specifications.

ESD Tolerance (Note 3)

Human Body	2.5 kV
Machine Model	250V
Supply Voltage ($V_{DD} - V_{SS}$)	18V
Storage Temperature Range	-65°C to +150°C
Junction Temperature (Note 4)	+150°C

Soldering Information

Infrared or Convection (20 sec.)	230°C
Wave Soldering (10 sec.)	260°C

Operating Ratings (Note 1)

Operating Temperature Range	-40°C to +105°C
Operating Voltage Range	6V to 16V
Package Thermal Resistance, θ_{JA} (Note 4)	84°C/W
48-Pin TSSOP	

16V Electrical Characteristics

Unless otherwise specified, all limits guaranteed for $T_J = 25^\circ\text{C}$, $V_{DD} = 16\text{V}$, $V_{SS} = 0\text{V}$, & $C_{LOAD} = 100\text{ pF}$ (Gamma & V_{COM} Buffers). **Boldface** limits apply at the temperature extremes. (Note 5)

Symbol	Parameter	Conditions	Min (Note 6)	Typ (Note 7)	Max (Note 6)	Units
Gamma Buffers

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications, see the Electrical Characteristics tables.

Note 2: When the output of the V_{COM} buffer exceeds the supply rails, while sinking or sourcing 100 mA, the V_{COM} output is susceptible to latch.

Note 3: Human body model, 1.5 k Ω in series with 100 pF. Machine model, 0 Ω in series with 200 pF

Note 4: The maximum power dissipation is a function of $T_{J(MAX)}$, θ_{JA} and T_A . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(MAX)} - T_A)/\theta_{JA}$. All numbers apply for packages soldered directly onto a PC board.

Note 5: Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing condition result in very limited self-heating of the device such that $T_J = T_A$. No guarantee of parametric performance is indicated in the electrical table under conditions of internal self-heating where $T_J > T_A$.

16V Electrical Characteristics (Continued)

Note 6: All limits are guaranteed by design or statistical analysis.

Note 7: Typical values represent the parametric norm at the time of characterization.

Note 8: Slew Rate is measured for $V_{IN} = 4 V_{PP}$. 10% -90% values are used. Slew rate is the average of the rising and falling slew rates

Note 9: 4 V_{PP} pulse (50 ns rise time) applied to one side of 100 pF series output capacitance, other side connected to output of buffer. Output to within 0.1% of input voltage.

Note 10: Linear output current measured at $|V_{OUT} - V_{IN}| = 0.1V$.

Note 11: This is a momentary test. Continuous large output currents may result in exceeding the maximum power dissipation and damage the device.

Note 12: Short circuit current measured at $|V_{OUT} - V_{IN}| = 1V$.

Application Section

INTRODUCTION

The performance capabilities of TFT-LCD's increase rapidly, with constant improvements such as larger sizes, higher resolution, and greater brightness. Today's LCD's have screen resolutions of over 1 Mega pixel and higher. The LM8207 can be used to improve the performance of an LCD. It is designed for buffering 18 gamma voltage levels and driving the V_{COM} level. These voltage levels can be derived from a highly stable Voltage Reference, which is included in the LM8207. The LM8207 meets the design requirements that combine technical improvement with the demand for cost effective solutions.

The following sections discuss the principle operation of a TFT-LCD and the principle operation of the LM8207 which includes sections on each of the following: the Voltage Reference, the Gamma Buffers, and the V_{COM} Buffer. After this, the next sections present a typical LM8207 configuration and consider the maximum power dissipation. The end of this application section introduces the evaluation board and presents layout recommendations.

PRINCIPLE OPERATION OF A TFT-LCD

This section offers a brief overview of the principle operating of TFT-LCD's. There is a detailed description of how information is presented on the display. An explanation of how data is written to the screen pixels and how the pixels are selected is also included.

20137930

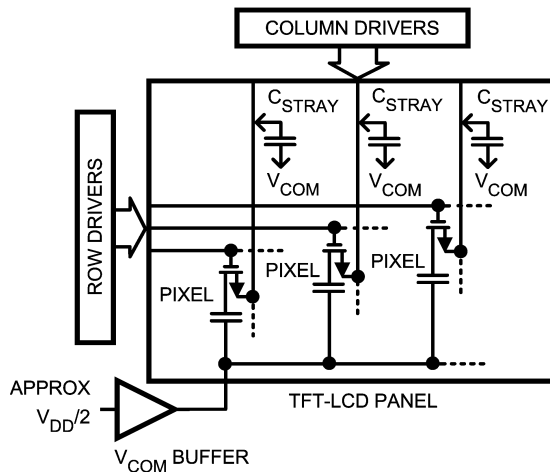

FIGURE 1. Individual LCD Pixel

Figure 1 shows a simplified illustration of an individual LCD pixel. The top and bottom plates of a pixel consist of Indium-Tin Oxide (ITO), which is a transparent, electrically conductive material. ITO lies on the inner surfaces of two glass substrates that are the front and back glass panels of a TFT display. Sandwiched between two ITO plates is an insulating material (liquid crystal). This alters the polarization of light, depending on how much voltage (V_{PIXEL}) is applied across the two plates. Polarizers are placed on the outer surfaces of the two glass substrates. In combination with the liquid

crystal, the polarizers create a variable light filter that modulates light transmitted from the back to the front of a display. A pixel's bottom plate lies on the backside of a display where a light source is applied, and the top plate lies on the front, facing the viewer. For most TFT displays, a pixel transmits the greatest amount of light when $V_{PIXEL} \leq \pm 0.5$ V, and it becomes less transparent as the voltage increases with either a positive or negative polarity.

For color displays, each pixel is built with three individual sub pixels. Each sub pixel represents a primary color. These colors are Red, Green and Blue (RGB). Combining these three primary colors every user-defined color can be created.

Figure 2 shows a simplified diagram of a TFT display, showing how individual pixels are connected to the row, column and V_{COM} driver. Each pixel is represented by a capacitor with a NMOS transistor connected to its top plate. Pixels in a TFT panel are arranged in rows and columns. Row lines are connected to the NMOS gates, and column lines to the NMOS sources. The back plate of every pixel is connected to a common voltage called V_{COM} . The voltage applied to the top plates (also called gamma voltage) controls the pixel brightness. The column drivers supply this gamma voltage via the column lines, and 'write' this voltage to the pixels one row at a time. This is accomplished by having the row drivers selecting an individual row of pixels when the column driver writes the gamma voltage levels. The row drivers sequentially apply a large positive pulse (typically 25V to 35V) to each row line. This turns on the NMOS transistors connected to an individual row, allowing voltage from the column lines to be written to the pixels.

20137931

FIGURE 2. TFT Display

The V_{COM} driver (buffer) supplies a common voltage (V_{COM}) to all the pixels in a TFT panel. V_{COM} is a constant DC voltage that is in the middle of the gamma voltage range. As a result, when a column driver writes to a row of pixels, the applied voltages are either positive or negative with respect to V_{COM} . In fact, the polarity of a pixel is reversed each time a row is selected, preventing a pattern from being 'burned' into the LCD.

Application Section (Continued)

FIGURE 3. Block Diagram of a Typical TFT-LCD

Figure 3 shows how the display information is refreshed. Using the row and column drivers, one pixel is addressed at the display. The column driver receives the digital color data from the timing controller. The corresponding gamma voltage will be determined, using the gamma correction curve. In fact, the gamma correction curve is just a voltage reference with 18 output tabs, which presets the color intensity settings. This gamma voltage is written to the pixel. The column driver selects one column at the time; the changing in the load may affect the 'tabs' of the gamma correction curve. This problem can be solved using 'gamma buffers' to isolate the gamma correction curve from the column driver.

PRINCIPLE OPERATION of the LM8207

The LM8207 combines three basic functions used in TFT displays:

- **Voltage Reference**

To improve picture quality and to reduce brightness variations, a highly stable reference voltage is available. It has a low drift over the operation temperature range. This output voltage (OUT_V_{REF}) is used as the reference voltage to define the gamma correction values.

- **Gamma Buffers**

The gamma correction curve can be defined easily using an external chain of precision resistors. To ensure load independent gamma correction levels, 18 gamma buffers, each having a low output resistance, can be used to drive the TFT display column drivers.

- **V_{COM} Buffer**

The V_{COM} buffer supplies a common voltage, which is applied to the back plate of all the pixels. Writing color information to all the pixels will cause high current variations at the V_{COM} level so this V_{COM} buffer is designed for driving large output currents.

These three functions are discussed in detail in the following sections.

VOLTAGE REFERENCE

The internal Voltage Reference of the LM8207 can be used to improve picture stability. This accurate reference is highly stable over the operation temperature range. The output voltage (OUT_V_{REF}) of the Voltage Reference can be set using two external resistors. In the next two sections, the possibilities for setting the output voltage of the Voltage Reference and the operating range of the Voltage Reference are discussed.

SETTING THE OUTPUT VOLTAGE OF THE VOLTAGE REFERENCE

The output voltage of the Voltage Reference Amplifier (OUT_V_{REF}) can be set using the internal reference in combination with the internal amplifier and two external resistors. In Figure 4 a typical application circuit for V_{REF} is given.

Application Section (Continued)

FIGURE 4. Typical Application Circuit for V_{REF}

To calculate the output voltage of the Voltage Reference Amplifier (OUT_V_{REF}) use the following equation:

$$\text{OUT_V}_{\text{REF}} = 1.295 \times \left(\frac{R_1 + R_2}{R_2} \right) + R_1 \times I_{\text{IN_V}_{\text{REF}}} \quad (1)$$

As can be seen in the Electrical Characteristics Table on page 3, $I_{\text{IN_V}_{\text{REF}}}$ has a typical value of -10 nA . Using resistor values for $R_1 = 9 \text{ k}\Omega$ and $R_2 = 1 \text{ k}\Omega$ this results in a gain of 10 and $\text{OUT_V}_{\text{REF}} = 12.95 \text{ V}$ an error will be introduced of $-10 \text{ nA} \times 9 \text{ k}\Omega = -90 \text{ }\mu\text{V}$. This error can be neglected. The simplified formula for calculating the $\text{OUT_V}_{\text{REF}}$ is:

$$\text{OUT_V}_{\text{REF}} = 1.295 \times \left(\frac{R_1 + R_2}{R_2} \right) \quad (2)$$

Example:

$$V_{\text{DD}} = 16\text{V}$$

$$\text{OUT_V}_{\text{REF}} = 14.4\text{V}$$

Choose $R_2 = 5 \text{ k}\Omega$. Using Equation (2), this will result in $R_1 = 50.6 \text{ k}\Omega$

THE OPERATING RANGE OF THE VOLTAGE REFERENCE

The output of the Voltage Reference Amplifier has a minimum of 1.295V ($R_1 = 0$). This is determined by the value of the internal reference. The maximum output voltage ($\text{OUT_V}_{\text{REFMAX}}$) can approach the positive supply rail V_{DD} . The voltage is limited by the output resistance (R_{OUT}) of the output stage of the internal amplifier and depends on the load current. Figure 5 shows the operating output voltage range.

FIGURE 5. Operating Output Voltage Range

The minimum headroom ($\text{OUT_V}_{\text{REF}}$ with respect to the positive supply rail V_{DD}) can be measured using the test circuit shown in Figure 6.

FIGURE 6. Headroom Test Circuit with Variable Output Current Load

The headroom is measured by varying both the supply voltage and the output current (I_{LOAD}) for a fixed programmed value of $\text{OUT_V}_{\text{REF}}$. As shown in Figure 7, the minimum headroom slightly increases for a constant V_{DD} when the load current increases.

Application Section (Continued)

20137922

FIGURE 7. Voltage Reference Headroom vs. Load Current

GAMMA BUFFERS

This section gives an overview for the applications of the gamma buffers and also defines the gamma correction curve. Specifications for the buffers are derived from their operation range. Also included are the formulas for the realization of the gamma correction curve using external resistors. An overview is given for the gamma voltage accuracy, using the LM8207 in combination with external resistors.

As discussed in the section entitled "Principle Operation of a TFT-LCD," the basic function of the gamma buffers is to make the gamma correction curve independent of the behavior of the column driver. Writing data to each subsequent pixel will cause load variations. The gamma buffers have a low impedance output and can handle these variations without changing the gamma correction curve. A typical gamma correction curve is given in Figure 8.

20137923

FIGURE 8. Typical Gamma Correction Curve

Each buffer covers a part of the correction curve and, therefore, has its own specifications. All buffers require that the output should recover quickly from disturbances caused by the switching of the column driver. The gamma voltage level of each buffer (VGMA1...VGMA18) depends on its position for the levels decrease sequentially. To best utilize the LM8207, each buffer is optimized for its position in the gamma correction curve.

- Gamma Buffers 1-2**

Operating voltage range: V_{DD} to $V_{SS} + 2V$. Due to the operating voltage, only negative transitions at the output are possible. Positive transitions will exceed the supply voltage V_{DD} . These buffers are able to source current to bias the resistive load of the column driver having an open collector structure. To meet the operating voltage range, these outputs need a resistive load connected to a lower potential sourcing an output current of at least 1 mA.

- Gamma Buffers 3-16**

Operating voltage range: $V_{DD} - 1V$ to $V_{SS} + 1V$. Due to the operating range, both positive and negative transitions at the outputs are possible.

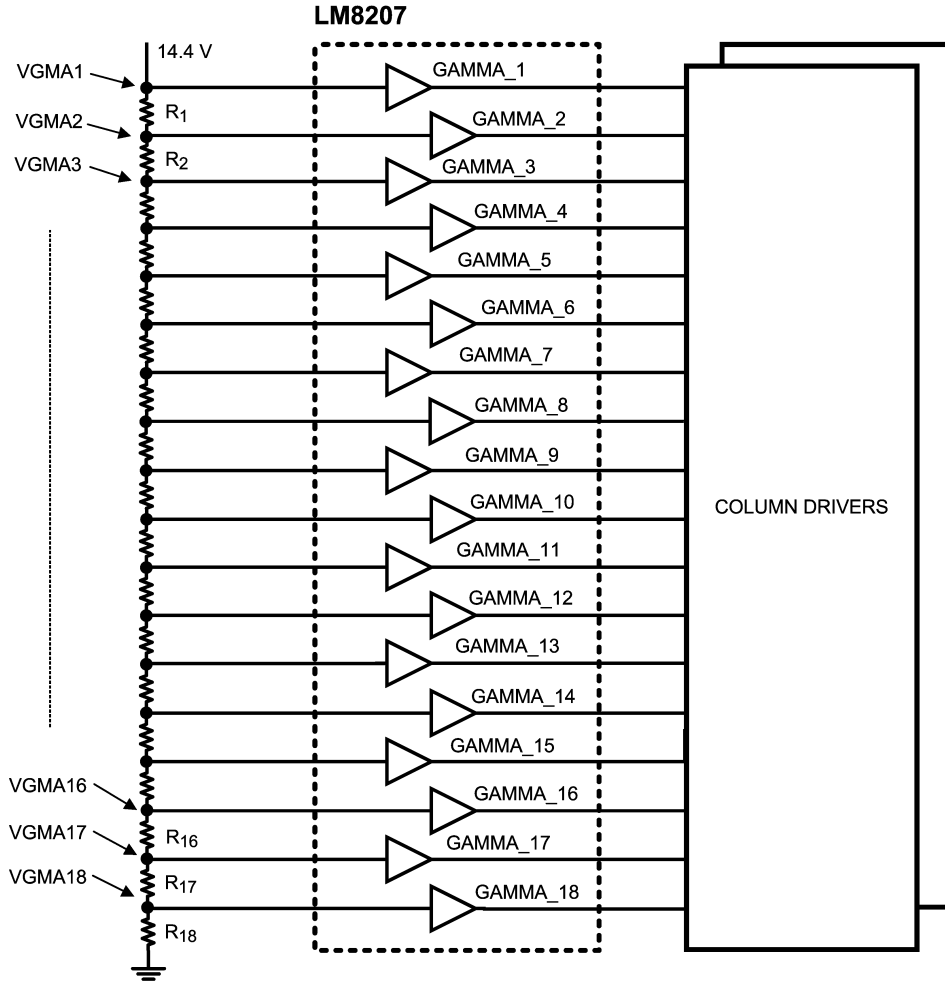

- Gamma Buffers 17-18**

Operating voltage range: $V_{DD} - 2$ to V_{SS} . Due to the operating voltage, only positive transitions at the output are possible. Negative transitions will exceed the negative supply voltage V_{SS} . These buffers are able to sink current from the resistive load of the column driver having an open collector structure. To meet the operating voltage range, these outputs need a resistive load connected to a higher potential sinking an output current of at least 1 mA.

Example:

A typical application using the LM8207 is given in Figure 9. The corresponding gamma correction curve (VGMA1...VGMA18) is defined in Table 1. The Voltage Reference supplies the 14.4V to the resistor network. The calculations for the resistor values and for setting the Voltage Reference are shown in the section "Voltage Reference."

Application Section (Continued)

20137927

FIGURE 9. Typical TFT Display Application Diagram Using the LM8207

The values of the resistors in the gamma correction curve are calculated such that a current of 1 mA flows in the resistor chain.

$$R_{18} = \left(\frac{VGMA_{18}}{I} \right) \text{ and } R_x = \left(\frac{VGMA_x}{I} \right) - \sum_{y=x+1}^{18} R_y$$

Where x is the index for the corresponding gamma voltage and has a range of 1 to 18.

Using these formulas the resistor values in *Table 1* are calculated. High accuracy resistors values can be realized using 0.1% resistors. A method for fine-tuning the resistor value is to combine two resistors in series.

Changing the gamma correction curve, in combination with the load of the column drivers can impact the behavior of the gamma buffers. Gamma buffers 1 and 2 are designed for operating voltages near V_{DD} , and will source the current into the column drivers. Gamma buffers 17 and 18 are designed for operating voltages near V_{SS} and will sink this current. Buffers 3 to 16 are designed to operate in the mid-voltage range and can sink or source current. Under special circumstances, by increasing the voltage gap between gamma buffer 1 and gamma buffer 2, in combination with a low impedance load of the column driver between these outputs, the output of buffer 2 has to sink more current than possible, and can saturate. This will result in a setting error of the inputs of the column driver.

For buffer 17 and 18 an identical situation can occur, by increasing the operating voltage range of buffer 17 with respect to buffer 18.

A simple and cost effective solution is to lower the resistance between buffer 2 and 3 or buffer 16 and 17, using an additional by-pass resistor R_S . This method is presented in *Figure 10*. This will not affect the desired voltage levels, and buffer 3 which has a larger linear output current spec will sink the current instead of buffer 2. The resistor value R_S can be calculated by the voltage drop divided by the current. The resistor value should be low enough to sink this current, otherwise buffer 2 and/or buffer 17 will still saturate.

FIGURE 10. Using additional by-pass resistor to increase current sinking capability

GAMMA VOLTAGE ACCURACY

Adding buffers to the tabs of the gamma correction resistor chain will make the values more independent of the load variations. Unfortunately, there are some other effects that will influence the gamma values. The following effects determine the accuracy of each gamma voltage.

Major effects are:

- Variation of the internal voltage reference. This can be found in the Electrical Characteristics Table. This is the maximum variation between parts.
- Variation of the feedback resistors used for setting the output voltage of the voltage reference (OUT_V_{REF}). Using high accuracy resistors will result in a small variation of the output voltage between different boards
- The accuracy of the resistors obtained from the gamma correction voltage curve. The gamma correction curve will be affected by the accuracy of the resistors. This will vary over different boards. Temperature variations will not affect this curve.
- Output offset voltage (V_{OS}) of the buffers. Variations of V_{OS} (output offset voltage) of the buffers, will affect the gamma correction curve. The contribution of V_{OS} is higher for the buffers driving the lower gamma voltages.

Minor effects are:

- Input current (I_{BIAS}) of the gamma buffers. Variations of the input current (I_{BIAS}) of the gamma buffers caused by temperature changes, will affect the gamma correction voltages.

Application Section (Continued)

V_{COM} BUFFER

The V_{COM} buffer supplies a common voltage to the back plate of all the pixels in a TFT panel. When column drivers write to the pixels, current pulses will occur onto the V_{COM} line. These pulses are the result of charging the capacitance between V_{COM} and the column lines. This capacitance is a combination of stray capacitance and pixel capacitance. This stray capacitance varies between panel sizes but typically ranges from 16 pF to 33 pF per column. Pixel capacitance is in the order of 0.5 pF and contributes very little to these pulses because only one pixel at a time is connected to a column. Charging this capacitance can result in short positive or negative current pulses of 100 mA or more, depending on the panel size. The V_{COM} buffer is designed to handle these pulses. A V_{COM} buffer is basically a voltage regulator that can sink or source current in large capacitive loads. The V_{COM} buffer should recover very fast from these disturbances. The operating voltage of the V_{COM} buffer is in the middle of the gamma voltage range.

20137928

FIGURE 11. V_{COM} Buffer

The typical application in *Figure 11* shows the V_{COM} buffer supplying a common voltage to the back plate of the display. This level can be adjusted by changing the value of the resistors. Increasing the value of R_1 or decreasing the value of R_2 will decrease the V_{COM} level. Increasing the value of R_2 or decreasing the value of R_1 will increase the V_{COM} level.

Another, more flexible, solution is to use National Semiconductor's programmable V_{COM} calibrator, the LM8342. The V_{COM} level can be adjusted using an I²C interface. See the LM8342's datasheet for more detailed information about this part.

LM8207 CONFIGURATION

A complete configured typical application of the LM8207 is given in *Figure 12*. All three basic functions of the LM8207 are discussed in the previous sections. Details for setting the Voltage Reference are given in the "Voltage Reference" section. Calculations for defining a gamma correction curve are given in the section entitled "Gamma Buffers." Defining and adjusting the V_{COM} level is discussed in the " V_{COM} Buffer" section. The LM8207 is an 18 channel gamma buffer plus a V_{COM} buffer. In certain applications some of the gamma buffers or the V_{COM} buffer may not be used. In such cases it is recommended that the unused buffer input pins be tied to the input voltage range value.

MAXIMUM POWER DISSIPATION

The maximum power dissipation in the LM8207 TSSOP package depends on the ambient temperature and the increase of the junction temperature of the die. Exceeding the maximum temperature will damage the part. (See the Absolute Maximum Ratings table on page 2 of the datasheet.) The V_{COM} buffer of the LM8207 is designed for use in pulsed conditions. Driving a continuous current of several hundred mA to a load will damage the part due to the high power consumption of the output stage of the V_{COM} buffer.

The maximum operating temperature can be calculated using this formula:

$$T_J = T_A + \theta_{JA} \times P_{DISSIPATION} \quad (3)$$

Where

- T_A = Ambient temperature
 θ_{JA} = Thermal resistance of package (See Operating Ratings table on page 2) (84°C/W)
 $P_{DISSIPATION}$ = Total power dissipation of the LM8207

Example:

The estimated power consumption of the LM8207 in a steady state situation with no load is:

$$\begin{aligned} V_{DD} &= 16V \\ I_{DD} &= 6 \text{ mA (all buffers within normal operating range)} \\ OUT_V_{REF} &= 14.4V \\ I_{LOAD} &= 3 \text{ mA} \\ V_{DD} \times I_{DD} &= 16 \text{ V} \times 6 \text{ mA} \\ (V_{DD} - OUT_V_{REF}) \times I_{LOAD} &= \\ (16 \text{ V} - 14.4 \text{ V}) \times 3 \text{ mA} &= 4.8 \text{ mW} \\ \text{Total steady state power dissipation} &= 100.8 \text{ mW} \end{aligned}$$

For an ambient temperature T_A of 40°C and a dissipated power of 100.8 mW, the junction temperature T_J will be 49°C. This will not exceed the maximum operating temperature.

Two issues are not considered in the calculation:

- Continuous power dissipation of the gamma buffers. This is load dependent, and can be calculated using the voltage drop over the output stage times the output current:
 $P = (V_{DD} - V_{GMAX}) \times I_{OUT}$ for current sourcing
 $P = (V_{GMAX}) \times I_{OUT}$ for current sinking
- Pulsed power dissipation of the buffers. The RMS value of this pulsed current depends on the magnitude of the current fluctuations and the duty cycle. This can majorly contribute to the total power dissipation.

Example:

When the LM8207 is in steady state biasing, the V buffer is considered at three various load conditions:

I_{OUTRMS} (mA)	V_{COM} Level (V)	Dissipation (mW)	Temp Rise	T_J
10	8	80	7	56
50	8	400	35	83
100	8	800	67	107

When $I_{OUTRMS} = 100 \text{ mA}$, the package (T_J) will exceed the Operating Temperature!

EVALUATION BOARD

For testing purposes an evaluation board is available. It is intended to evaluate the following functions:

- The Voltage Reference is fully adjustable within the operating range. For optimal output voltage ranges, user defined resistors can be trimmed by using two resistors in series.
- The Gamma correction curve is user defined using external resistors. Each optimal value can be achieved by using two series resistors for fine-tuning.
- The V_{COM} node input voltage can be achieved using National Semiconductor's LM8342 programmable V_{COM} calibrator, or using an external supply.
- For testing, an additional dummy load can be connected to all outputs of the gamma buffers.

LAYOUT RECOMMENDATIONS

A proper layout is necessary for optimum performance of the LM8207. A low impedance and clean ground plane is recommended. The traces from the V_{SS} pin to the ground plane should be as short as possible. Decoupling capacitors should be placed very close to the V_{DD} pin. Connections of these decoupling capacitors to the ground plane should be very short. An additional decoupling capacitor for OUT_V_{REF} is recommended.

Due to the heavy current peaks and short transitions at the V_{COM} node, traces from the output of the V_{COM} buffer should be low impedance and as short as possible, to minimize both voltage drops over the trace and unwanted EM disturbances.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

- Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
- A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

BANNED SUBSTANCE COMPLIANCE

National Semiconductor manufactures products and uses packing materials that meet the provisions of the Customer Products Stewardship Specification (CSP-9-111C2) and the Banned Substances and Materials of Interest Specification (CSP-9-111S2) and contain no "Banned Substances" as defined in CSP-9-111S2.

Leadfree products are RoHS compliant.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
